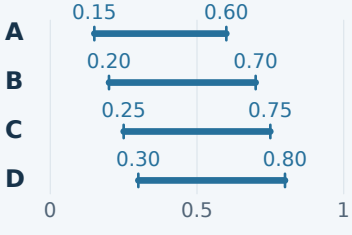
(a) One confidence view

Observational intervals



Randomized group means

$(m_A + m_C)/2 = 0.65$

$(m_B + m_D)/2 = 0.70$

Fixed snapshot + assumptions

(b) Can this policy guarantee a gain?

Requested gain: $\delta = 0.100$ percentage points (pp)

			Verified lower bound
Q1	No saved proof	→ **Solve + check** save constraint weights →	**+1.000 pp**
Q2	+0.638 pp > δ	→ **Reuse + check** →	**+0.638 pp**
Q3	-2.250 pp < δ	→ **Solve + check** →	**+0.500 pp**

Insufficient reuse triggers a solve, not policy rejection.

(c) What is the best possible guarantee?

Disjoint groups: cap means → allocate → recover a policy

Policy lower bound **2.500 pp** = Family upper bound **2.500 pp**

Optimal robust guarantee

Feasible $m = (.6, .7, .7, .7)$
